## CSC 311: Introduction to Machine Learning

Lecture 7 - Probabilistic Models

Amanjit Singh Kainth

University of Toronto, Summer 2025

#### Outline

- Probabilistic Modeling of Data
- Discriminative and Generative Classifiers
- Naïve Bayes Models
- Bayesian Parameter Estimation

#### Today

- So far in the course we have adopted a modular perspective, in which the model, loss function, optimizer, and regularizer are specified separately.
- Today we begin putting together a probabilistic interpretation of our model and loss, and introduce the concept of maximum likelihood estimation.

Probabilistic Modeling of Data

- Probabilistic Modeling of Data
- 2 Discriminative and Generative Classifiers
- Naïve Bayes Models
- Bayesian Parameter Estimation

#### Example: A Biased Coin

You flip a coin N=100 times and get outcomes  $\{x_1,\ldots,x_N\}$  where  $x_i\in\{0,1\}$  and  $x_i=1$  is interpreted as heads H.

Suppose you had  $N_H=55$  heads and  $N_T=45$  tails.

We want to create a model to predict the outcome of the next coin flip. That is, we want to answer this question:

What is the probability it will come up heads if we flip again?

#### Model

The coin may be biased. Let's assume that one coin flip outcome x is a Bernoulli random variable for a currently unknown parameter  $\theta \in [0,1]$ .

$$p(x=1|\theta)=\theta$$
 and  $p(x=0|\theta)=1-\theta$  or more succinctly  $p(x|\theta)=\theta^x(1-\theta)^{1-x}$ 

Assume that  $\{x_1, \ldots, x_N\}$  are independent and identically distributed (i.i.d.). Thus, the joint probability of the outcome  $\{x_1, \ldots, x_N\}$  is

$$p(x_1, ..., x_N | \theta) = \prod_{i=1}^N \theta^{x_i} (1 - \theta)^{1 - x_i}$$

6

#### **Loss Function**

The likelihood function is the probability of observing the data as a function of the parameters  $\theta$ :

$$L(\theta) = \prod_{i=1}^{N} \theta^{x_i} (1 - \theta)^{1 - x_i}$$

We usually work with log-likelihoods (why?):

$$\ell(\theta) = \sum_{i=1}^{N} x_i \log \theta + (1 - x_i) \log(1 - \theta)$$

7

#### Maximum Likelihood Estimation

How can we choose  $\theta$ ? Good values of  $\theta$  should assign high probability to the observed data.

The maximum likelihood criterion says that we should pick the parameters that maximize the likelihood.

$$\hat{\theta}_{\mathrm{ML}} = \operatorname*{arg\,max}_{\theta \in [0,1]} \ell(\theta)$$

We can find the optimal solution by setting derivatives to zero.

$$\frac{\mathrm{d}\ell}{\mathrm{d}\theta} = \frac{\mathrm{d}}{\mathrm{d}\theta} \left( \sum_{i=1}^{N} x_i \log \theta + (1 - x_i) \log(1 - \theta) \right) = \frac{N_H}{\theta} - \frac{N_T}{1 - \theta}$$

where  $N_H = \sum_i x_i$  and  $N_T = N - \sum_i x_i$ .

Setting this to zero gives the maximum likelihood estimate:

$$\hat{\theta}_{\rm ML} = \frac{N_H}{N_H + N_T}.$$

#### Maximum Likelihood Estimation

- define a model that assigns a probability (or has a probability density at) to a dataset
- · maximize the likelihood (or minimize the neg. log-likelihood).

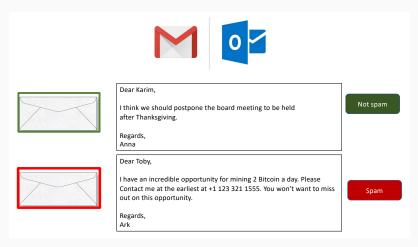

Discriminative and Generative

Classifiers

- Probabilistic Modeling of Data
- Discriminative and Generative Classifiers
- Naïve Bayes Models
- Bayesian Parameter Estimation

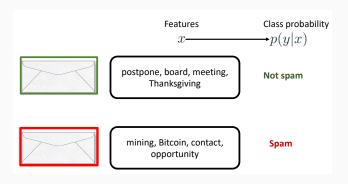

#### Spam Classification

For a large company that runs an email service, one of the important predictive problems is the automated detection of spam email.

#### Discriminative Classifiers

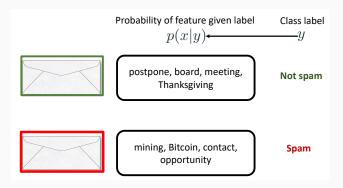

**Discriminative** classifiers try to learn mappings directly from the space of inputs  $\mathcal{X}$  to class labels  $\{0, 1, 2, \dots, K\}$ 

#### **Generative Classifiers**

**Generative** classifiers try to build a model of "what data for a class looks like", i.e. model  $p(\mathbf{x}, y)$ . If we know p(y) we can easily compute  $p(\mathbf{x}|y)$ .

Classification via Bayes rule (thus also called Bayes classifiers)

#### Generative vs Discriminative

- Discriminative approach: estimate parameters of decision boundary/class separator directly from labeled examples.
  - ▶ Model  $p(t|\mathbf{x})$  directly (logistic regression models)
  - ► Learn mappings from inputs to classes (linear/logistic regression, decision trees etc)
  - ► Tries to solve: How do I separate the classes?
- Generative approach: model the distribution of inputs characteristic of the class (Bayes classifier).
  - ▶ Model  $p(\mathbf{x}|t)$
  - ► Apply Bayes Rule to derive  $p(t|\mathbf{x})$ .
  - ► Tries to solve: What does each class "look" like?
- · Key difference: is there a distributional assumption over inputs?

Naïve Bayes Models

- Probabilistic Modeling of Data
- 2 Discriminative and Generative Classifiers
- Naïve Bayes Models
- Bayesian Parameter Estimation

#### **Example: Spam Detection**

- · Classify email into spam (c = 1) or non-spam (c = 0).
- Binary features  $\mathbf{x} = [x_1, \dots, x_D], x_i \in \{0, 1\}$  saying whether each of D words appears in the e-mail.

Example email: "You are one of the very few who have been selected as a winner for the free \$1000 Gift Card."

#### Feature vector for this email:

- ...
- "card": 1
- ..
- · "winners": 1
- · "winter": 0
- ...
- "you": 1

#### Bayesian Classifier

Given features  $\mathbf{x}=[x_1,x_2,\cdots,x_D]^T$  want to compute class probabilities using Bayes Rule:

$$\underbrace{p(c|\mathbf{x})}_{\text{Pr. class given feature}} = \frac{\underbrace{p(\mathbf{x}|c)}_{p(\mathbf{x}|c)} \underbrace{p(c)}_{p(\mathbf{x})}$$

In words,

$$\mbox{Posterior for class} = \frac{\mbox{Pr. of feature given class} \times \mbox{Prior for class}}{\mbox{Pr. of feature}}$$

To compute  $p(c|\mathbf{x})$  we need:  $p(\mathbf{x}|c)$  and p(c).

#### Motivation for Compact Representation

- Two classes:  $c \in \{0, 1\}$ .
- Binary features  $\mathbf{x} = [x_1, \dots, x_D], x_i \in \{0, 1\}$
- Define a joint distribution  $p(c, x_1, \dots, x_D)$ . How many probabilities do we need to specify this joint dist.?
- Let's impose structure on the distribution so that the representation is compact and allows for efficient learning and inference

#### Naïve Bayes Independence Assumption

#### Naïve assumption:

the features  $x_i$  are conditionally independent given the class c.

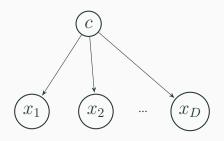

· Allows us to decompose the joint distribution:

$$p(c, x_1, \dots, x_D) = p(c) p(x_1|c) \cdots p(x_D|c).$$

Compact representation of the joint distribution

- Prior probability of class:  $p(c=1)=\pi$  (e.g. prob of spam)
- Conditional probability of feature given class:  $p(x_j=1|c)=\theta_{jc}$  (e.g. prob of word appearing in spam)

#### Bayesian Network for a Naive Bayes Model

We can form a graphical model.

- · Which probabilities do we need to specify this dist.?
- How many probabilities do we need to specify this dist.?

#### Decomposing the Log-Likelihood

Decompose the log-likelihood into independent terms.

Optimize each term independently.

$$\begin{split} \ell(\boldsymbol{\theta}) &= \sum_{i=1}^{N} \log p(c^{(i)}, \mathbf{x}^{(i)}) = \sum_{i=1}^{N} \log \left\{ p(\mathbf{x}^{(i)}|c^{(i)}) p(c^{(i)}) \right\} \\ &= \sum_{i=1}^{N} \log \left\{ p(c^{(i)}) \prod_{j=1}^{D} p(x_{j}^{(i)} \mid c^{(i)}) \right\} \\ &= \sum_{i=1}^{N} \left[ \log p(c^{(i)}) + \sum_{j=1}^{D} \log p(x_{j}^{(i)} \mid c^{(i)}) \right] \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{D} \sum_{j=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{D} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{j=1}^{N} \sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(x_{i}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(x_{i}^{(i)} \mid c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}) \\ &= \sum_{i=1}^{N} \log p(c^{(i)}) + \sum_{i=1}^{N} \log p(c^{(i)}$$

#### Learning the Prior over Class

- To learn the prior, we maximize  $\sum_{i=1}^{N} \log p(c^{(i)})$
- Define  $\pi = p(c^{(i)} = 1)$
- Pr. *i*-th email:  $p(c^{(i)}) = \pi^{c^{(i)}} (1-\pi)^{1-c^{(i)}}$ .
- · Log-likelihood of the dataset:

$$\sum_{i=1}^{N} \log p(c^{(i)}) = \sum_{i=1}^{N} c^{(i)} \log \pi + \sum_{i=1}^{N} (1 - c^{(i)}) \log(1 - \pi)$$

• Maximum likelihood estimate of the prior  $\pi$  is the fraction of spams in dataset.

$$\hat{\pi} = \frac{\sum_{i} \mathbb{1}[c^{(i)} = 1]}{N} = \frac{\text{\# spams in dataset}}{\text{total \# samples}}$$

#### Learning Pr. Feature Given Class

- To learn  $p(x_j^{(i)} = 1 \,|\, c)$ , we maximize  $\sum_{i=1}^N \log p(x_j^{(i)} |\, c^{(i)})$
- Define  $\theta_{jc} = p(x_j^{(i)} = 1 \mid c)$ .
- Pr. of *i*-th email:  $p(x_j^{(i)} | c) = \theta_{jc}^{x_j^{(i)}} (1 \theta_{jc})^{1 x_j^{(i)}}$ .
- · Log-likelihood of the dataset:

$$\sum_{i=1}^{N} \log p(x_j^{(i)} | c^{(i)}) = \sum_{i=1}^{N} c^{(i)} \left\{ x_j^{(i)} \log \theta_{j1} + (1 - x_j^{(i)}) \log(1 - \theta_{j1}) \right\}$$
$$+ \sum_{i=1}^{N} (1 - c^{(i)}) \left\{ x_j^{(i)} \log \theta_{j0} + (1 - x_j^{(i)}) \log(1 - \theta_{j0}) \right\}$$

• Maximum likelihood estimate of  $\theta_{jc}$  is the fraction of word j occurrances in each class in the dataset.

$$\hat{\theta}_{jc} = \frac{\sum_{i} \mathbb{1}[x_j^{(i)} = 1 \ \& \ c^{(i)} = c]}{\sum_{i} \mathbb{1}[c^{(i)} = c]} \quad \overset{\text{for } c = 1}{=} \quad \frac{\text{\#word } j \text{ appears in class } c}{\text{\# class } c \text{ in dataset}}$$

#### Predicting the Most Likely Class

- We predict the class by performing **inference** in the model.
- · Apply Bayes' Rule:

$$p(c \mid \mathbf{x}) = \frac{p(c)p(\mathbf{x} \mid c)}{\sum_{c'} p(c')p(\mathbf{x} \mid c')} = \frac{p(c) \prod_{j=1}^{D} p(x_j \mid c)}{\sum_{c'} p(c') \prod_{j=1}^{D} p(x_j \mid c')}$$

• For input **x**, predict c with the largest  $p(c)\prod_{j=1}^{c}p(x_{j}\mid c)$  (the most likely class).

$$p(c \mid \mathbf{x}) \propto p(c) \prod_{j=1}^{D} p(x_j \mid c)$$

#### Naïve Bayes Properties

- · An amazingly cheap learning algorithm!
- Training time: estimate parameters using maximum likelihood
  - ► Compute co-occurrence counts of each feature with the labels.
  - ► Requires only one pass through the data!
- Test time: apply Bayes' Rule
  - ► Cheap because of the model structure. (For more general models, Bayesian inference can be very expensive and/or complicated.)
- · Analysis easily extends to prob. distributions other than Bernoulli.
- Less accurate in practice compared to discriminative models due to its "naïve" independence assumption.

# Bayesian Parameter Estimation

- Probabilistic Modeling of Data
- 2 Discriminative and Generative Classifiers
- Naïve Bayes Models
- Bayesian Parameter Estimation

#### **Data Sparsity**

Maximum likelihood can overfit if there is too little data.

Example: what if you flip the coin twice and get H both times?

$$\theta_{\rm ML} = \frac{N_H}{N_H + N_T} = \frac{2}{2+0} = 1$$

The model assigned probability 0 to T. This problem is known as data sparsity.

#### Defining a Bayesian Model

We need to specify two distributions:

• The prior distribution  $p(\theta)$  encodes our beliefs about the parameters before we observe the data.

• The likelihood  $p(\mathcal{D} \mid \boldsymbol{\theta})$  encodes the likelihood of observing the data given the parameters.

#### The Posterior Distribution

 When we update our beliefs based on the observations, we compute the posterior distribution using Bayes' Rule:

$$p(\boldsymbol{\theta} \mid \mathcal{D}) = \frac{p(\boldsymbol{\theta})p(\mathcal{D} \mid \boldsymbol{\theta})}{\int p(\boldsymbol{\theta}')p(\mathcal{D} \mid \boldsymbol{\theta}') d\boldsymbol{\theta}'}.$$

- · Rarely ever compute the denominator explicitly.
- In general, computing the denominator is intractable.

#### Revisiting Coin Flip Example

We already know the likelihood:

$$L(\theta) = p(\mathcal{D}|\theta) = \theta^{N_H} (1 - \theta)^{N_T}$$

It remains to specify the prior  $p(\theta)$ .

- An uninformative prior, which assumes as little as possible.
   A reasonable choice is the uniform prior.
- But, experience tells us 0.5 is more likely than 0.99.
   One particularly useful prior is the beta distribution:

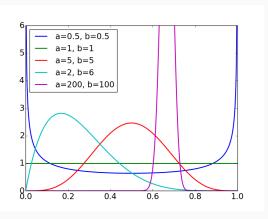

$$p(\theta; a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \theta^{a-1} (1-\theta)^{b-1}.$$

We can ignore the normalization constant.

$$p(\theta; a, b) \propto \theta^{a-1} (1 - \theta)^{b-1}$$
.

#### **Beta Distribution Properties**

- The expectation is  $\mathbb{E}[\theta] = a/(a+b)$ .
- $\cdot$  The distribution gets more peaked when a and b are large.
- When a = b = 1, it becomes the uniform distribution.

#### Posterior for the Coin Flip Example

Computing the posterior distribution:

$$p(\boldsymbol{\theta} \mid \mathcal{D}) \propto p(\boldsymbol{\theta})p(\mathcal{D} \mid \boldsymbol{\theta})$$

$$\propto \left[ \theta^{a-1} (1-\theta)^{b-1} \right] \left[ \theta^{N_H} (1-\theta)^{N_T} \right]$$

$$= \theta^{a-1+N_H} (1-\theta)^{b-1+N_T}.$$

A beta distribution with parameters  $N_H + a$  and  $N_T + b$ .

• The posterior expectation of  $\theta$  is:

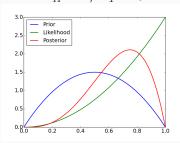

$$\mathbb{E}[\theta \mid \mathcal{D}] = \frac{N_H + a}{N_H + N_T + a + b}$$

- Think of a and b as pseudo-counts. beta(a,b) = beta(1,1) + a-1 heads + b-1 tails.
- The prior and likelihood have the same functional form (conjugate priors).

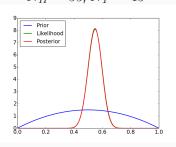

#### Bayesian Inference for the Coin Flip Example

When you have enough observations, the data overwhelm the prior.

# Small data setting $N_H = 2$ . $N_T = 0$

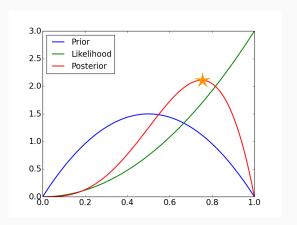

## Large data setting $N_H = 55$ . $N_T = 45$

#### Maximum A-Posteriori (MAP) Estimation

Finds the most likely parameters under the posterior (i.e. the mode).

#### Maximum A-Posteriori Estimation

Converts the Bayesian parameter estimation problem into a maximization problem

$$\begin{split} \hat{\boldsymbol{\theta}}_{\text{MAP}} &= \arg\max_{\boldsymbol{\theta}} \ p(\boldsymbol{\theta} \,|\, \mathcal{D}) \\ &= \arg\max_{\boldsymbol{\theta}} \ p(\boldsymbol{\theta}) \, p(\mathcal{D} \,|\, \boldsymbol{\theta}) \\ &= \arg\max_{\boldsymbol{\theta}} \ \log p(\boldsymbol{\theta}) + \log p(\mathcal{D} \,|\, \boldsymbol{\theta}) \end{split}$$

#### Maximum A-Posteriori Estimation

Joint probability of parameters and data:

$$\begin{split} \log p(\theta, \mathcal{D}) &= \log p(\theta) + \log p(\mathcal{D} \,|\, \theta) \\ &= \operatorname{Const} + (N_H + a - 1) \log \theta + (N_T + b - 1) \log (1 - \theta) \end{split}$$

Maximize by finding a critical point

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\log p(\theta, \mathcal{D}) = \frac{N_H + a - 1}{\theta} - \frac{N_T + b - 1}{1 - \theta} = 0$$

Solving for  $\theta$ ,

$$\hat{\theta}_{\text{MAP}} = \frac{N_H + a - 1}{N_H + N_T + a + b - 2}$$

## Estimate Comparison for Coin Flip Example

$N_H = 55, N_T = 45$	$N_H = 2, N_T = 0$	Formula	
$\frac{55}{100} = 0.55$	1	$\frac{N_H}{N_H + N_T}$	$\hat{ heta}_{ m ML}$
$\frac{57}{104} \approx 0.548$	$\frac{4}{6} \approx 0.67$	$\frac{N_H + a}{N_H + N_T + a + b}$	$\mathbb{E}[\theta \mathcal{D}]$
$\frac{56}{102} \approx 0.549$	$\frac{3}{4} = 0.75$	$\frac{N_H + a - 1}{N_H + N_T + a + b - 2}$	$\hat{ heta}_{ ext{MAP}}$

 $\hat{\theta}_{\mathrm{MAP}}$  assigns nonzero probabilities as long as a,b>1.
